Topic of this video:

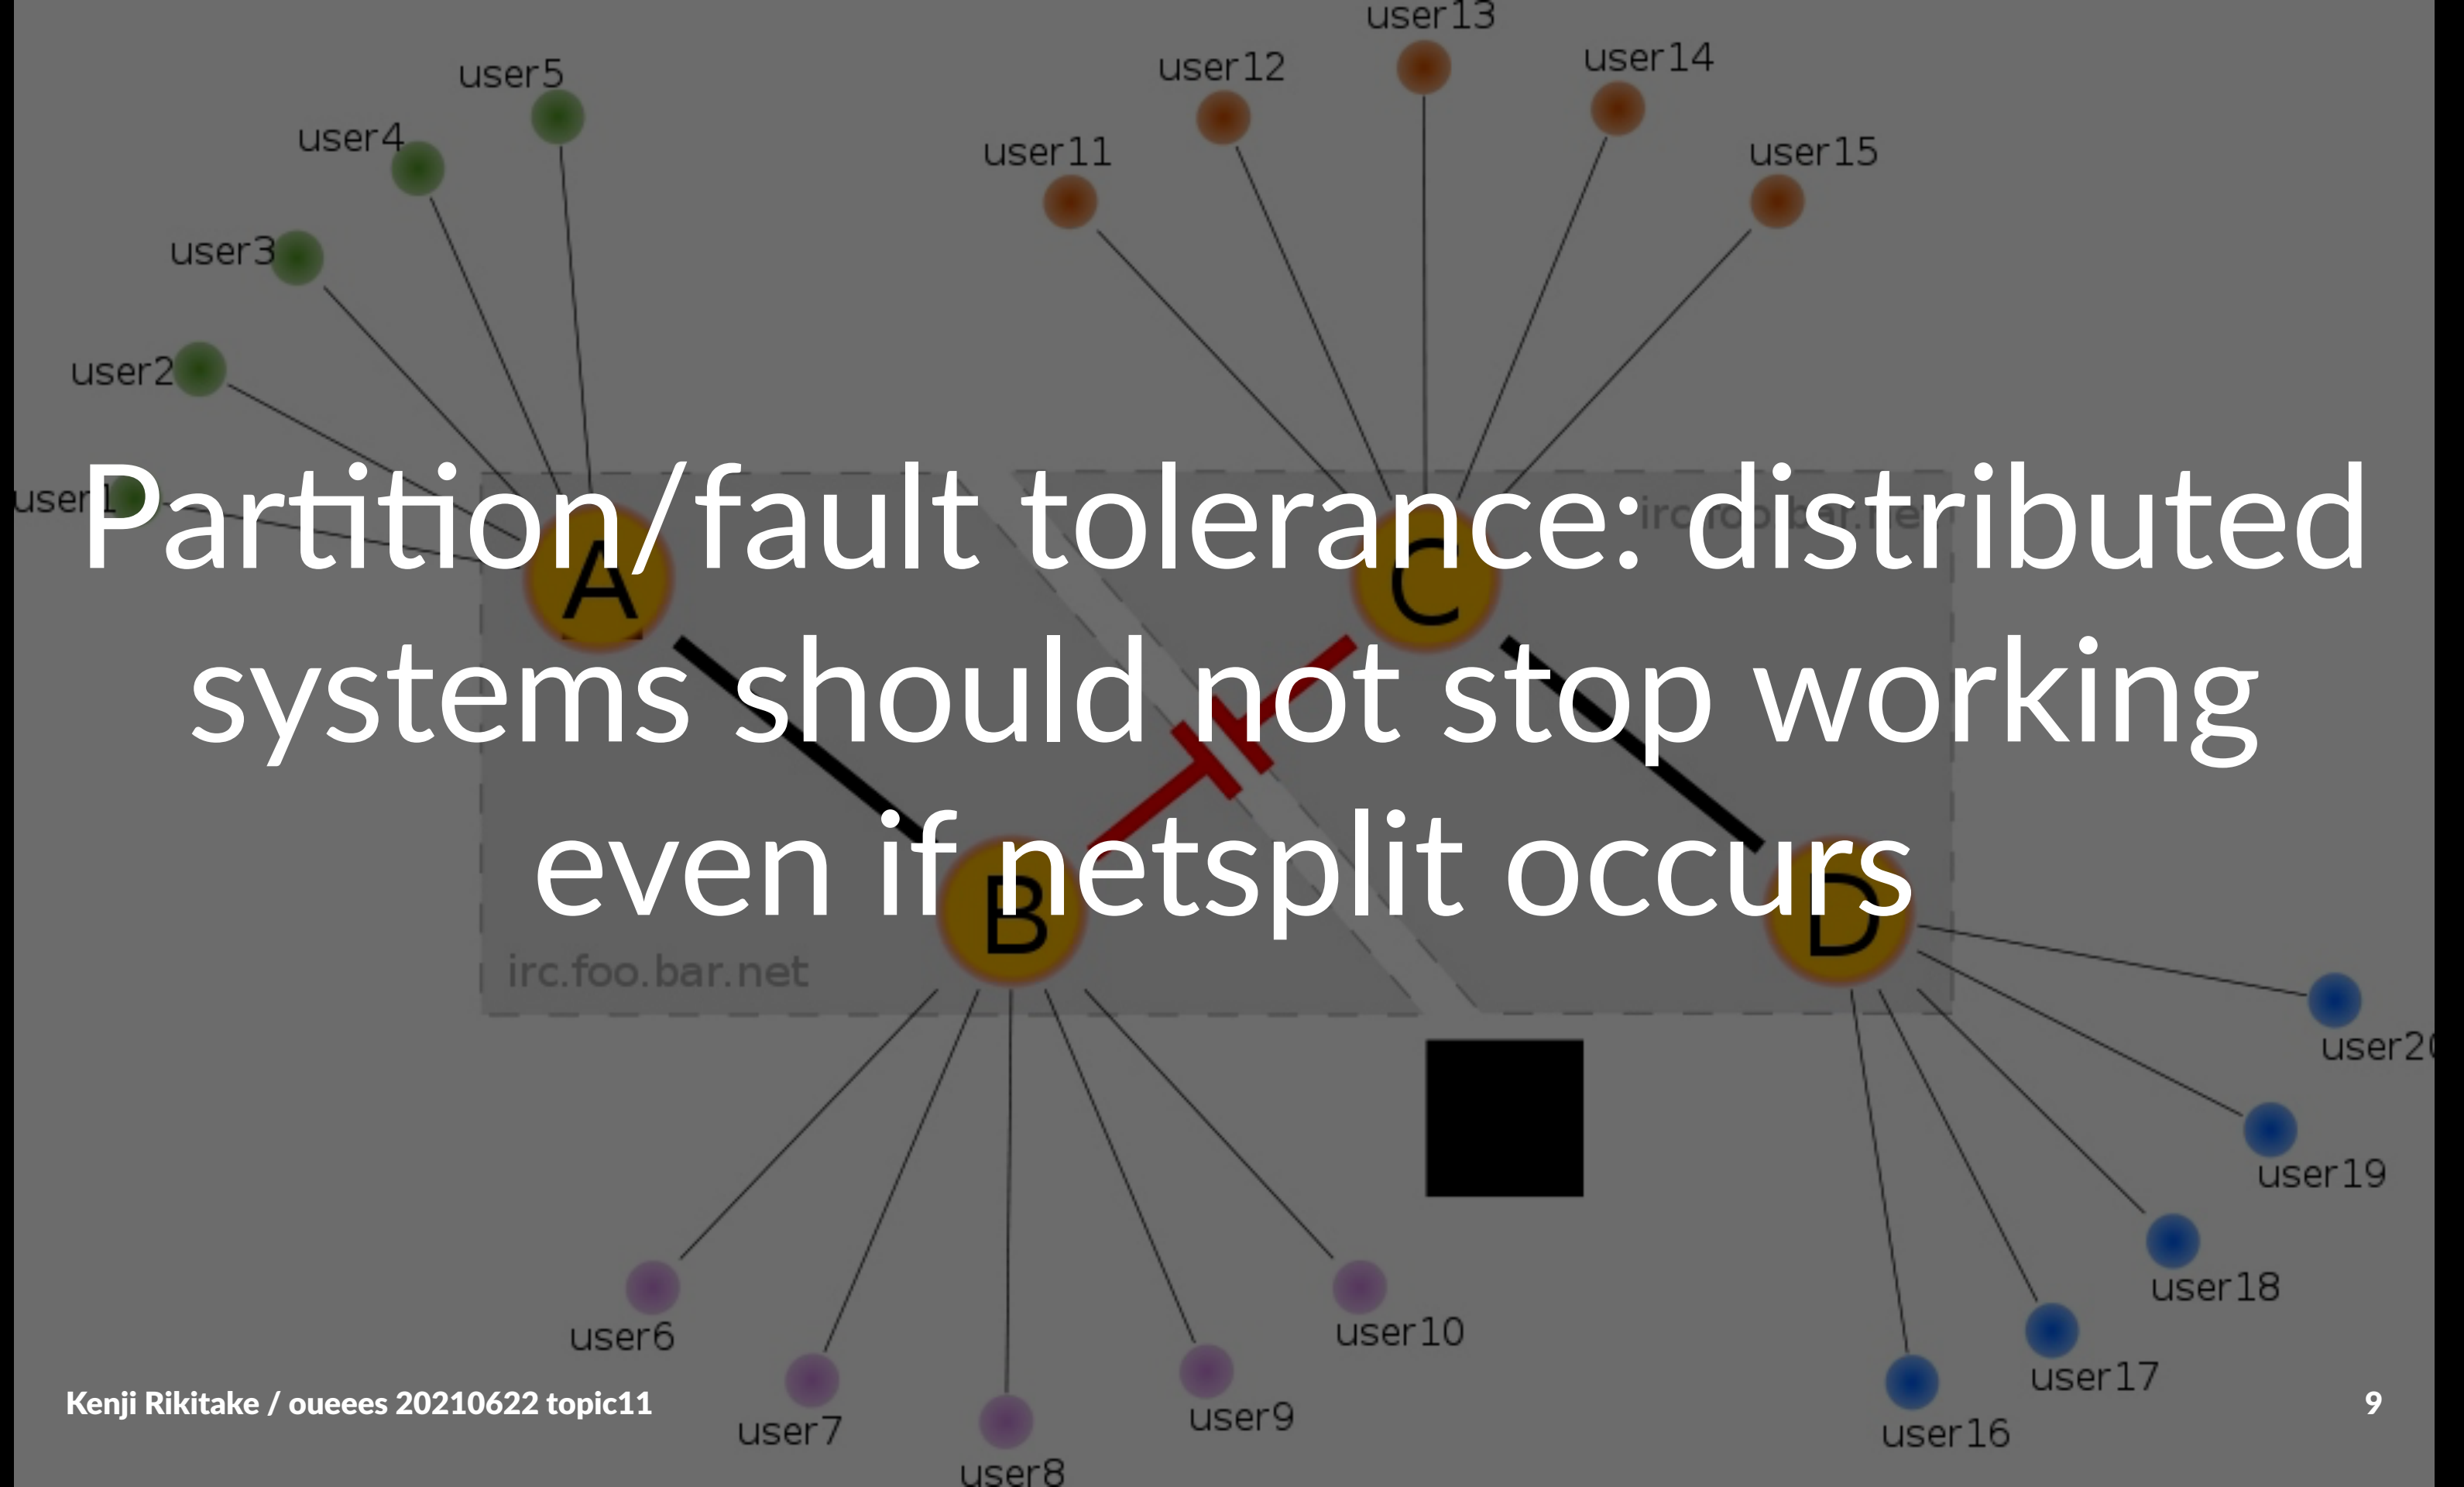

Network fault-tolerance

Networks *split*

Real-world challenges

- Natural disasters
- Device failures
- Human operation errors
- Political impediments
- Social resentments

Handling *failures*

- Redundancy: keeping backup units ready
- Fault tolerance: keeping systems running even the components fail
- Resilience by failing fast: early detection of failures and invocation of the recovery procedures

Why fault tolerance?

- Hard disk MTBF \approx 1 million hours
- 1000 hard disks running 24 hours x 365 days = 8.76 million hours
- If you're running a system with 1000 hard disks, **9 out of 1000** will fail in a year
- Recovery of a disk content takes often *a day*; you can't stop a system for *a day*, can you?

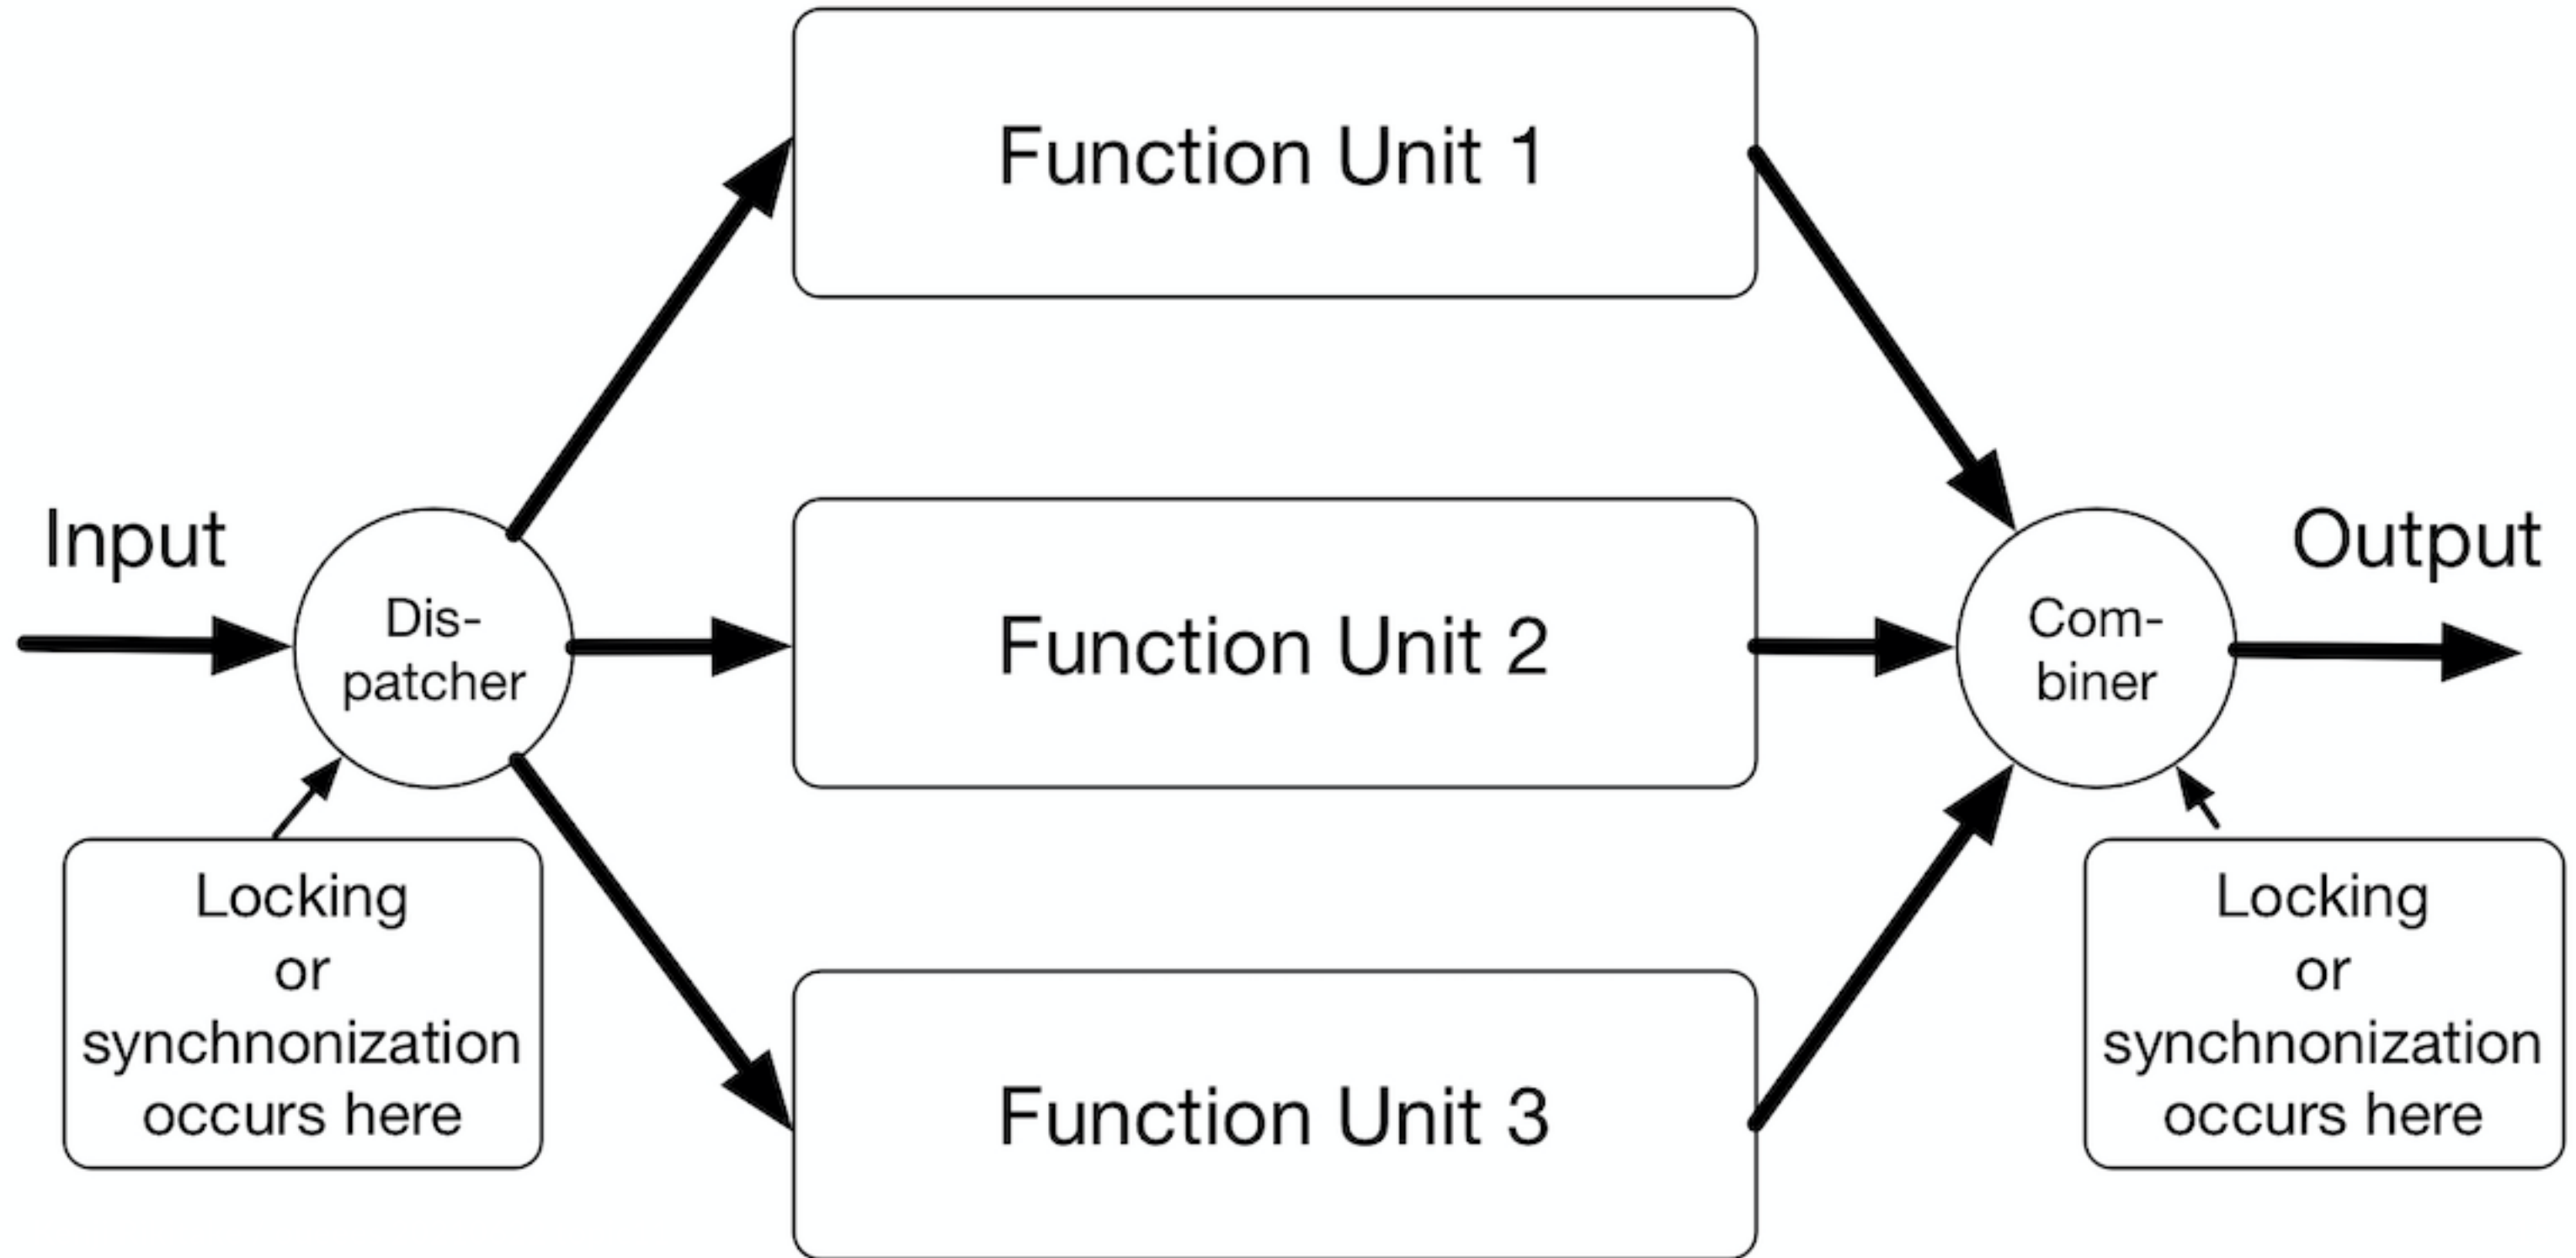

Requirement to keep the systems fault tolerant

- Redundancy: two or more resources for each unit of processing
- Supervising the failure of the units by an independent supervisor
- Rollback capability: undo the incomplete operations and retry

Consistency issues of distributed systems

- Locking/synchronization: waiting all data to be ready to compute or proceed to next step
- Choosing the *right* data: which data is *correct*?
- Supervision: fault detection and restarting

Each function unit runs on
its own speed

Supervision
tree example

Try to
restart

when
crashed

Eight Fallacies of Distributed Computing³ (1/2)

- **The network is reliable**
- **Latency is zero**
- **Bandwidth is infinite**
- The network is secure

³ <https://blog.fogcreek.com/eight-fallacies-of-distributed-computing-tech-talk/>

Eight Fallacies of Distributed Computing (2/2)

- Topology doesn't change
- There is one administrator
- Transport cost is zero
- The network is homogeneous

Summary: centralized computing is fragile; distributed computing is fault tolerant but hard
